05/20/2004

Advanced Biomedical Computing Center

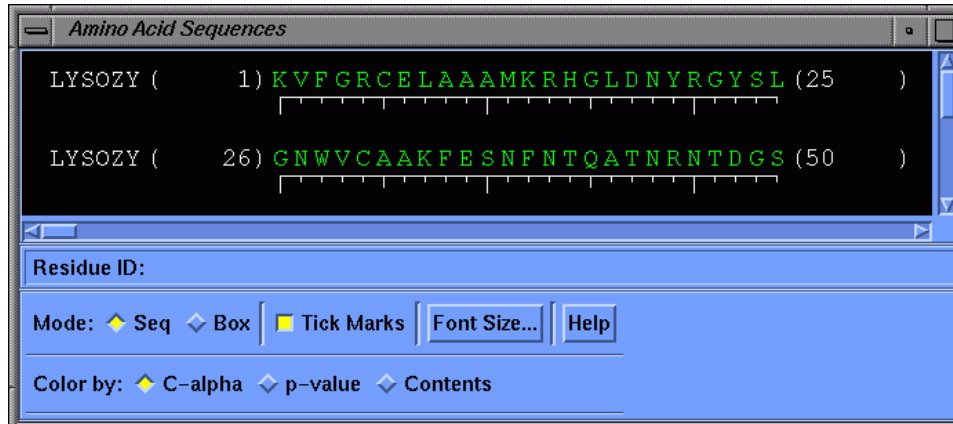

- Supercomputing facility located at NCI-Frederick (Bldg 430)
 - NCI, NIH, NIA
- What do we do?
Consultation, Training, Research
- Biomedical Research groups at ABCC
 - Quantum-Mechanics, Molecular Modeling, Bioinformatics, Structural Biology...
- Web: <http://www-fbnc.ncifcrf.gov>

Overview

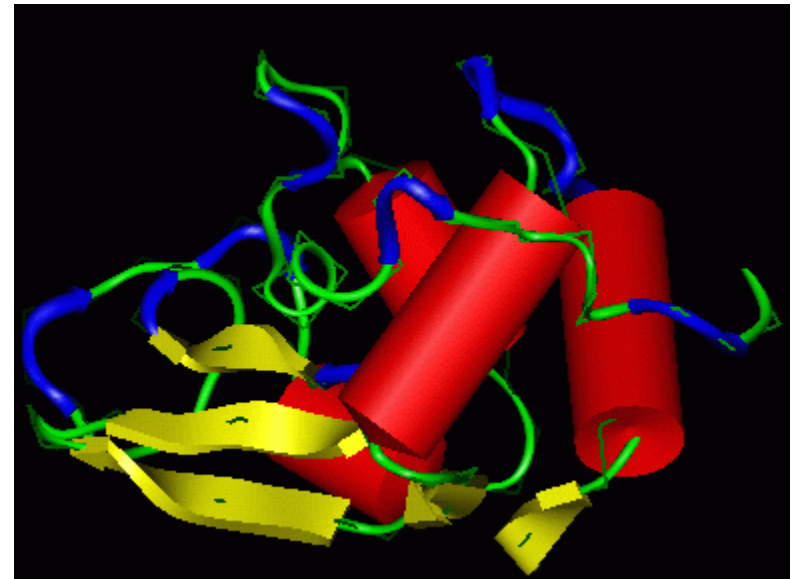

- Basics of Homology Modeling
- Hands-on exercise
 - Homology Modeling using Sybyl
 - Homology Modeling using InsightII
- What I will not talk about!
 - Alternatives to Comparative (homology) modeling
 - Basics of protein structure (primary, secondary...)
 - Theory behind sequence alignment (pair-wise and Multiple) and scoring matrices
 - Theory behind the Sybyl (Composer) and InsightII (homology) modules

Overview of Homology Modeling

3D-Structure

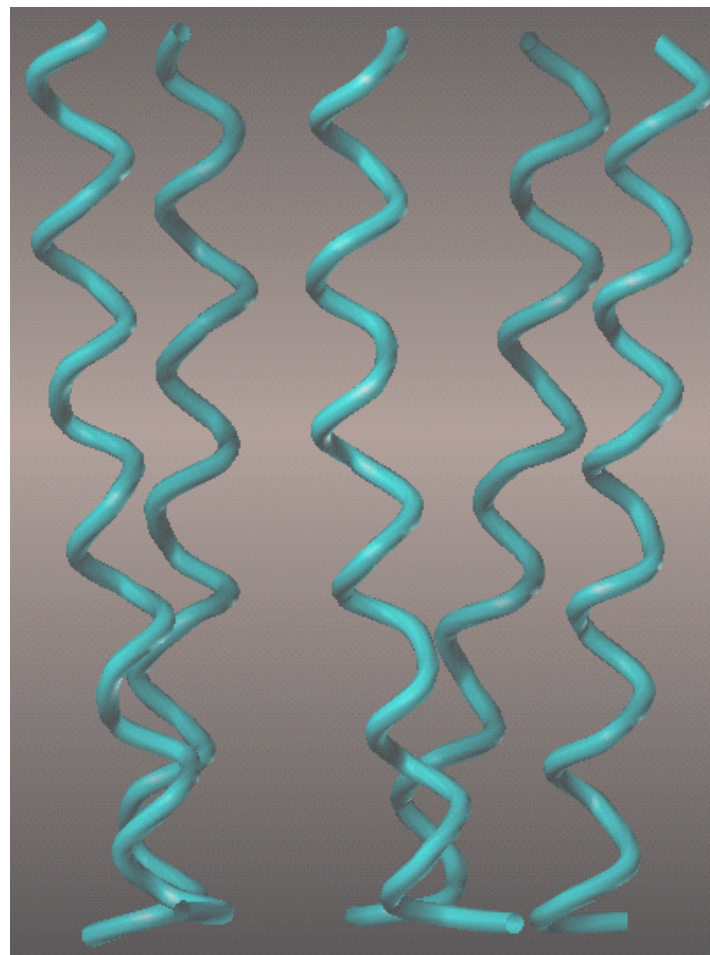

Accelrys: Homology

Why Homology Modeling?

- Rate of structure solving through NMR or X-ray is slow compared to the deposition of DNA and Protein sequences
 - Crystallization is the bottle-neck (time in months). No generic recipe for crystallization
 - Swiss-Prot Release 43.3 as of 05/10/04 151047 entries
 - PDB as of 05/18/04 has 25,551 structures
 - PDB: 25,115 (13-Apr-04); Sw-Pr: release 43.1 (148516) (13 Apr 04)
- Membrane proteins are difficult to crystallize
 - 30% of proteome of living things
- Knowledge of 3D structure is essential for the understanding of the protein function
- Structural information enhances our understanding of protein-protein or protein-DNA interactions

Applications of Homology Modeling

- Potassium Channel proteins
 - Trans-membrane region-no 3D structure available
 - Used Homology Modeling to build a model for the channel protein
 - Used QSAR to model the binding of inhibitors
 - Docking to study the drug-receptor interaction

Jozwiak, Wainer, Ravichandran and Collins, J. Med. Chem 2004

Homologous Proteins

- Homologous Proteins:
 - “Having a common evolutionary origin”
 - Evolved evolutionarily from a common ancestor
- Many of the essential proteins (key regulators) present in humans are also present in other living organisms (eg. Rat, bacteria)
- These essential proteins have to conserve their functionality throughout evolution
 - DNA polymerases
 - DNA replication
 - Necessary for all organisms
 - MHC Major Histocompatibility Complex
 - Antigen presentation to trigger an immune response
 - Present in higher Eukaryotes, rats and humans

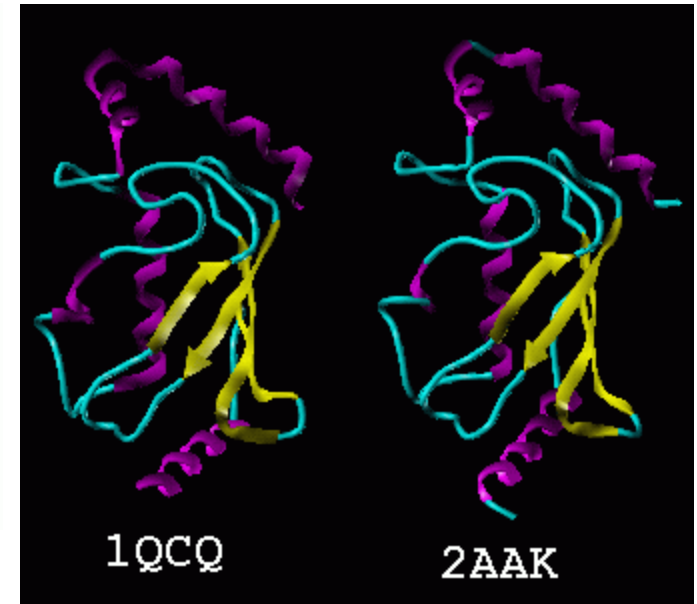

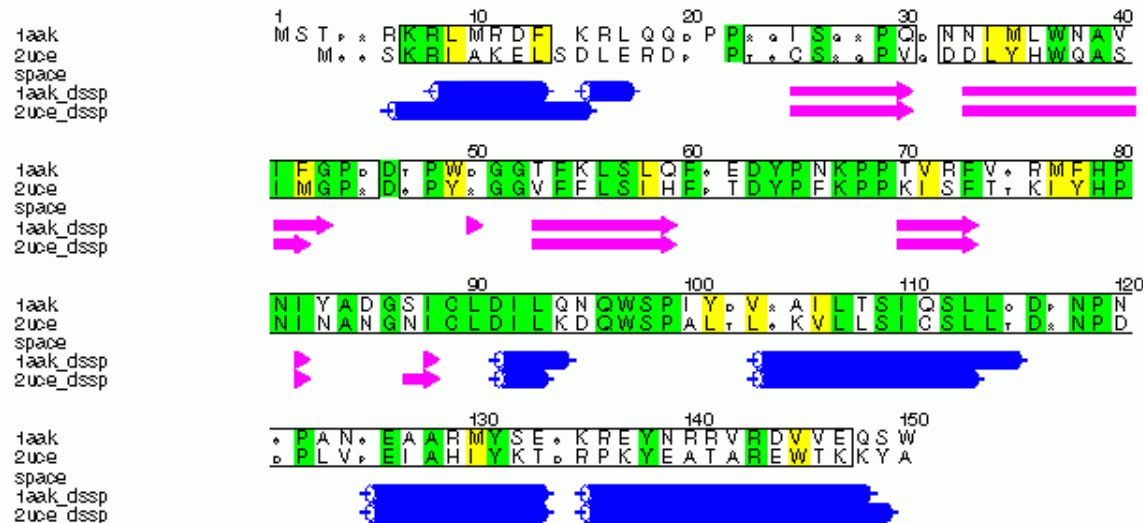

How to identify homologous proteins? Can we exploit sequence information?

Comparing Homologous enzymes

Family: Ubiquitin Conjugating enzyme

1QCQ: Arabidopsis Thaliana 2AAK: Baker's Yeast

Sequence Identity 43%

Russell et al, JMB, **269**, 423-439 1997

Sequence Dissimilarity & Structural Similarity

What we already know about homologous proteins

- Core region is pretty much conserved (main secondary structural features)
- Most dissimilarity is observed in the surface (loop) regions
- Within homologous proteins secondary-structures can move relative to each other or even disappear but neither order nor orientation will differ (α becoming β etc.)
- Sequence similarity is less conserved compared to Structural similarity
 - Far diverged proteins has very little sequence similarity

Sequence Dissimilarity & Structural Similarity

Doolittle's Rule of thumb:

- Sequences longer than 100 aa and has more than
 - 25% identity (with appropriate gaps): Very likely related
 - 15-25% identity: May still be related
 - < 15% probably not
 - How do we make sure that the alignment in the <15% (twilight zone) is biologically meaningful
 - » Random Shuffling-Random mutations and comparison with original score to make sure that the alignment is not random

Homology Modeling: Terminology & Basic Assumptions

Terminology:

- Protein sequence we are modeling is called the *Target*
- Homologous protein used in the modeling is called the *Template*

Basic Assumptions

- Similar sequences have similar conformations
- Core regions provide excellent template for modeling the target protein. If the Core regions share 50% identity, then the two proteins can almost always be superimposed with an RMSD of 1 Å or less

3D Structure Database

- PDB
 - Brookhaven National Laboratories
 - Research Collaboratory for Structural Bioinformatics (RCSB)-Collaborative effort NIST, Rutgers and San Diego Super Computing Facility
 - <http://www.rcsb.org>
 - Publically available 3-D structures of Proteins, Proteins + Nucleic Acids (DNA), Proteins complexed with metals and inhibitor
 - Experimental methods: X-ray and NMR

NMR & X-ray

- NMR

- Dynamic
 - **Multiple Models (Each conformation is a model)**
- Aqueous environment
- Limitations
 - Size of molecule
 - < 30kD

- Example

- 1DV0, 1UBA

- X-ray

- Static
 - Only one model
- Crystal
- Limitations
 - Not limited by size

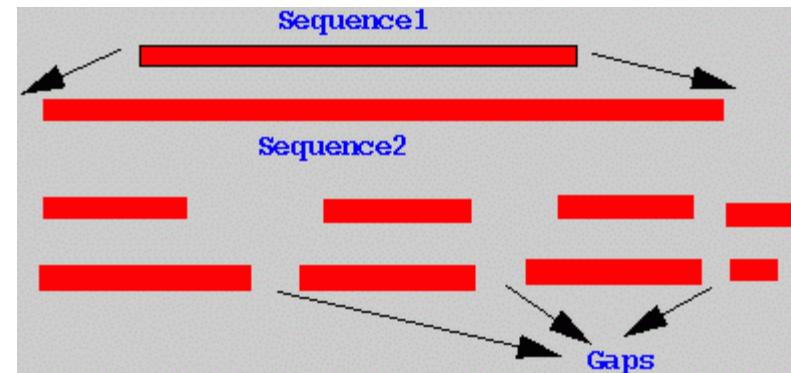

- Examples

- 7LYZ

Database mining

- Why Sequence Comparison?
- Template sequences:
 - Global Alignment
 - Overall alignment sequence homologs with known 3-D str.
- Sequences of both template & target: Local Alignment
 - Best for searching local domains
 - Gaps cannot be introduced endlessly
 - Biologically meaningless

GA_CGGATTAG
GA⁻TCGGAATAG
Local Alignment

Global Alignment

Scoring Schemes

- Scheme based on Identity
- " based on Chemical Similarity
- " based on Genetic Code
- " based on Observed Mutations

Example of Identity Scoring Scheme

Sequence 1 **GACGGATTAG**; Sequence 2 **GATCGGAATAG**

Total Score

$$9 \times 1 + 1 \times (-1) + 1 \times (-2) = 6$$

Dynamic Programming

Global alignment

G	A	-	C	G	G	A	T	T	A	G
G	A	T	C	G	G	A	A	T	A	G
1	1	-2	1	1	1	1	-1	1	1	1

PAM BLOSUM

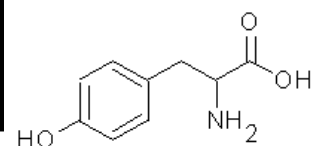

- PAM (Dayhoff et al 1988)
 - PAM1 is the matrix obtained by comparing sequences differ by no more than 1%
 - Higher PAMX are extrapolated from PAM1)
 - PAM250: Observed difference(80%) Evolutionary distance (250)
- Limitation: Matrices are derived from alignments of sequence that are 85% identity
 - Difficult to use in Twilight Zone
- Blosum (BLOcks SUBstitution Matrix) Heinkoff & Heinkoff (1992)
 - Derived from BLOCKS database
 - Distant relationships explained better than PAM
 - Blosum62 obtained from sequence BLOCKS clustered at $\geq 62\%$ identity
 - BlosumX are observed from actual alignments not extrapolated
 - Sequences are very similar use higher Blosum (low PAM)

PAM250 Matrix (identities at 20% level)

	Ala	Arg	Asn	Asp	Cys	Gln	Glu	Gly	His	Ile	.
Ala	2	-2	0	0	-2	0	0	1	-1	-1	
Arg	-2	6	0	-1	-4	1	-1	-3	2	-2	
Asn	0	0	2	2	-4	1	1	0	2	-2	
Asp	0	-1	2	4	-5	2	3	1	1	-2

Ile	-1	-2	-2	-2	-2	-2	-2	-3	-2	5	
.											

Tryptophan : Highly conserved-
Hydrophobic core residue-Important
for the structure-difficult to mutate.
Trp->Phe, Trp->Tyr (aromatic acids are
the next choice to replace Trp)

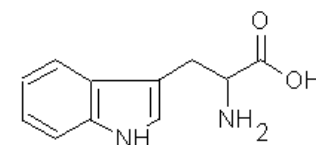

Cystein: Well-known for S-S linkage
Important for structure

Tyrosine (Tyr)

Phenylalanine (Phe)

Tryptophan (Trp)

Unitary Matrix

	A	C	G	T
A	1	0	0	0
C	0	1	0	0
G	0	0	1	0
T	0	0	0	1

05/20/04

NCI-Frederick

Searching for Templates

- Do a Blast/Fasta or use programs within GCG (Align, gap, bestfit, etc.) for sequence alignment. Restrict search only to PDB database
why PDB?
- Potentially suitable templates
 - Blast Score < 0.001 (protein), $\leq 10^{-6}$ (nucleotide)
 - Safe threshold is $> 25\text{-}30\%$ identity
 - In the Twilight Zone ($< 25\%$) How to proceed?
 - Randomization of sequences and realignment
- Usually more than one protein is chosen as templates?
 - Avoid biasing, to model variants (loops etc), side chain conformations
 - Final model will be done using one representative template (called reference)

Structurally Conserved Region (SCR) Modeling

- After identifying template(s), the next task is to identify the SCR

- What are SCRs?

```
L ( 1) K V Y G R C E L A A A M K R L G L D N Y R G Y S L G N W V C A A K F E - S N F N T H (41)
I H L ( 1) K V Y G R C E L A A A M K R H G L D K Y Q G Y S L G N W V C A A K F E - S N F N T Q (41)
H E L ( 1) K V F G R C E L A A A M K R H G L D N Y R G Y S L G N W V C A A K F E - S N F N T Q (41)
G H L ( A0) K V Y G R C E L A A A M K R M G L D N Y R G Y S L G N W V C A A K F E - S N F N T G (A41)
L Z 1 ( 1) K V F E R C E L A R T L K L G M D G Y R G I S L A N W M C L A K W E - S G Y N T R (41)
A L C ( 1) k g f t k c e l s q n l - - y d i d g y g r i a l p e l i c - t m f h t s g y d t q (39)
```

- Inner core (not the surface exposed loops)
- How do we identify them?
 - Multiple Sequence Alignments, secondary structure elements
- What happens when we have only one template?
- The next step is to align the Structurally aligned templates with the unknown sequence
 - No gaps are allowed within the SCR regions
 - Special sequence alignment algorithm used which discourages gaps within SCR.

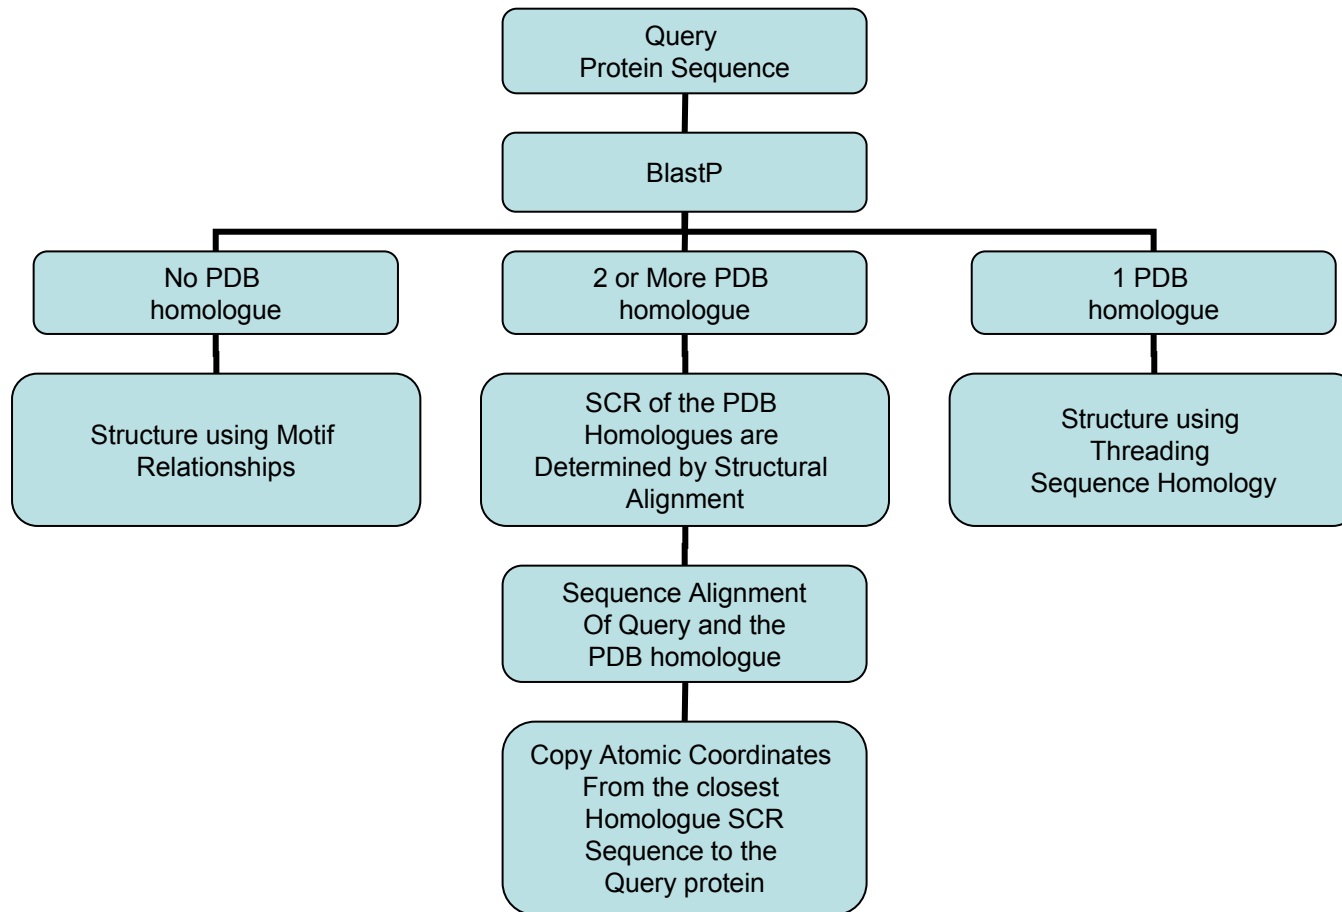

Structurally Variable Region (SVR) Modeling (3 methods)

- If the reference protein has similar loops then it can be copied
- Perform a database (derived from PDB) search for structures with loops
 - Criterion is the conserved residues flanking the loop area and the # of loop residues
 - Software usually keep a loop database derived from PDB.
- *de novo* method of building and constrained minimization
 - If the number of residues in the template and the reference differ
- Mostly MM calculations carried out as the last step

Modeling Side Chains

- Given that each side chain can be in one of many different conformations—Multiple minima problem
- Following options are generally used:
 - If the residues are same/similar
 - Copy the same conformation (why?—scoring matrix scores)
 - If they are different
 - Use built-in libraries based on known info (PDB)
 - Random conformations without any collisions
- Residues in the border (SCR,SVR) have to be dealt carefully

Overview of Homology Modeling

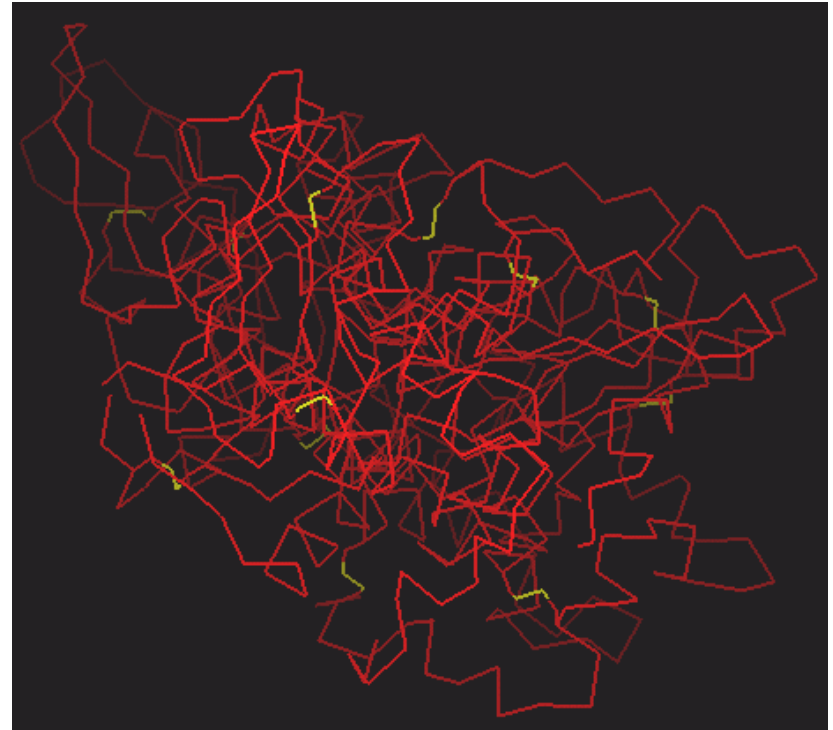

Homology Modeling By Example

Homology Module of InsightII

Template Alignment

- 5 **template** lysozyme proteins (only α -C shown) structurally uncorrected multiple sequence alignment
- Reference **Red**
- Query Sequence **violet**

Studying the corrected template alignment

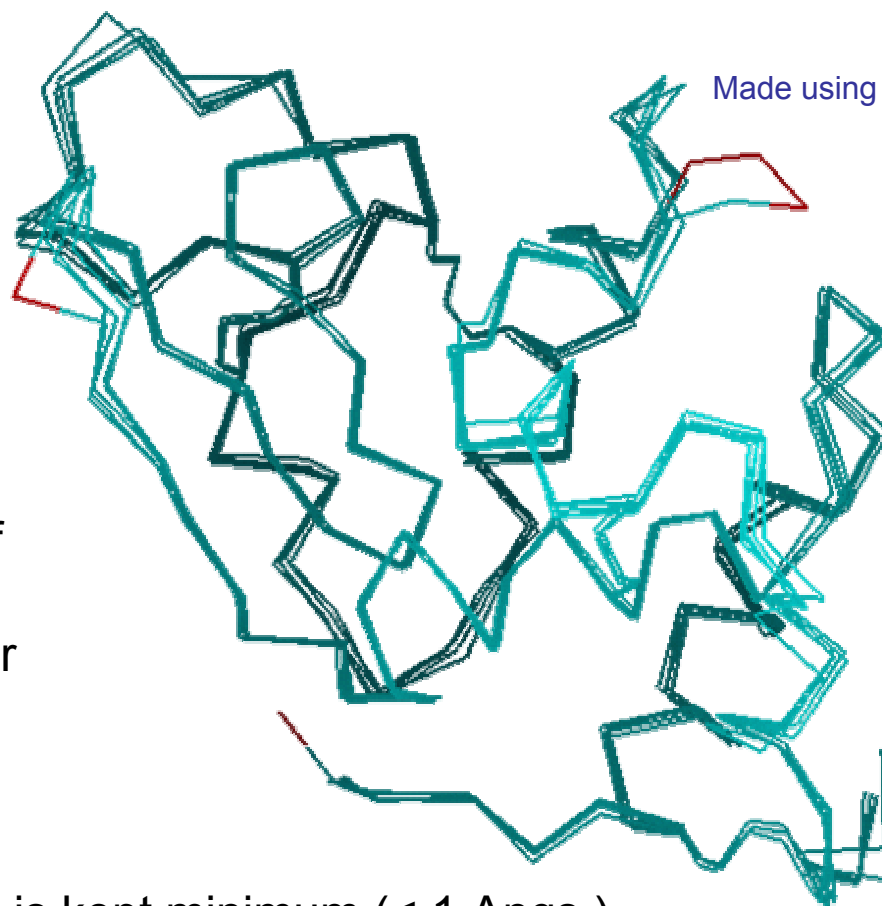

- Look at cys

How about the
Structural Conservation?

- Which regions show structural variation?

Structurally corrected MSA

Made using InsightII, Accelrys

Do you see
the location of
the variable
region (core or
surface)

	A	B
A	0	0.5
B	0.5	0

RMS deviation is kept minimum (< 1 Angs.)
Structurally corrected MSA

Target Core Modeling

- Target sequence is aligned with the template or Structurally Corrected Multiple Sequence alignment (in case of templates)
 - Which residues can be aligned to the conserved block region of the multiple sequence alignment of the reference protein so that one can copy the coordinates from the reference to the sequence
 - Do a sequence alignment using a chosen matrix, gap penalty etc. of the reference with the model sequence

Target Core Modeling

- Target sequence is now aligned with the template or Structurally Corrected Multiple Sequence alignment (in case of templates)

Made using InsightII, Accelrys

```
L ( 1) K V Y G R C E L A A A M K R L G L D N Y R G Y S L G N W V C A A K F E S N F N T H (41)

```

Made using InsightII, Accelrys

Gap insertion

Suspect the alignment

- Look at the alignment and if the gaps introduced are not in the surface exposed then go examine the parameters of the alignment (gap-penalty etc.)
- If the deletions occur at the end-terminus, surface exposed, not in any recognized secondary structure, then they may be valid deletions
- Finally, copy the coordinates from each conserved group of one of the most similar sequence template to the model sequence.
 - Other alternative is “Distance Geometry” approach

- 1) Before alignment 2) wrong alignment parameters 3) correct alignment parameters (higher gap penalty)

Loop Modeling

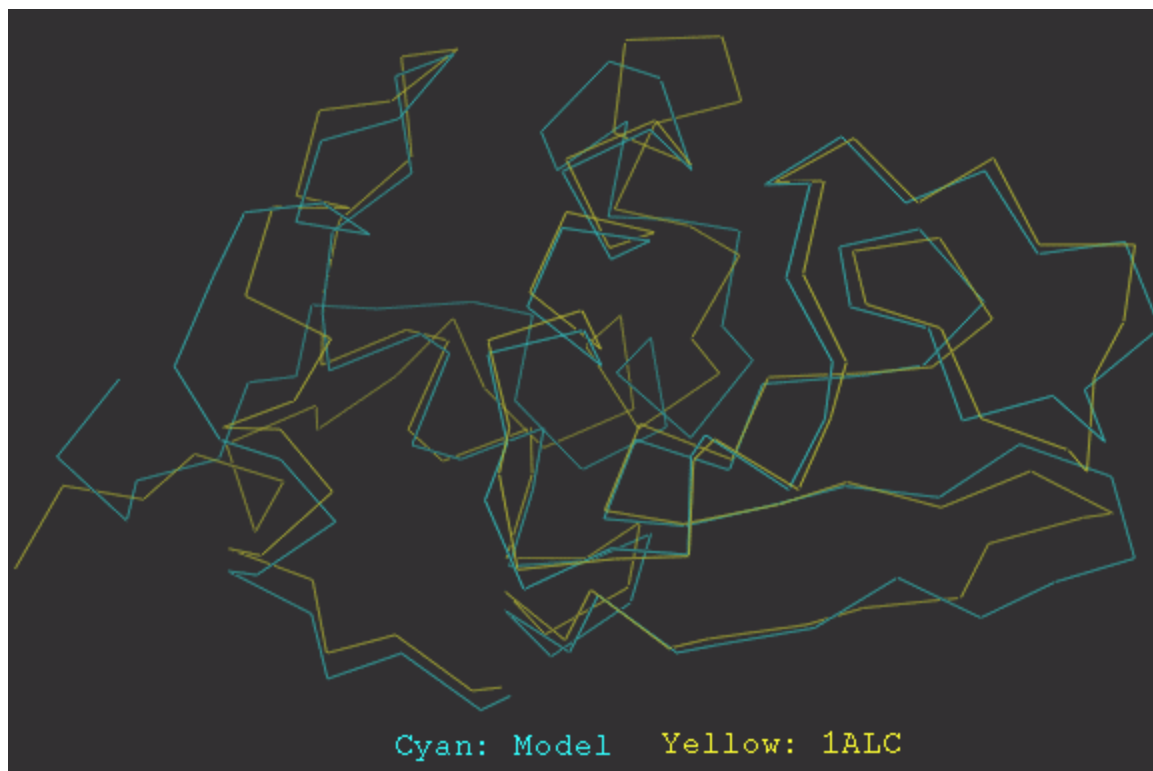

Side Chains will be added
if the template has
identical residues

Rotamers will be
generated which doesn't
clash with the backbone

Final Model

Homology Model Evaluation

- Most automated Homology Modeling software provides a model, even with an inappropriate template
- How to judge the quality of the model?
 - Absence of R-factors-No way to evaluate the model
 - One option is to look at Luzzati plot
 - Correct models usually have atomic positions within the experimental uncertainty limit

Final Step: Energy Minimization

- Why? The final model now has backbone+side-chains+loops generated from the template(s)
 - Has atom clashes and non-optimal conformations
- Choose a program to perform Energy Minimization to repair the model structure (bad contacts)
 - Swiss-Model uses GROMOS
- How many steps of Minimization ?
 - Vacuum (non-solvent)

Identifying Incorrect Models

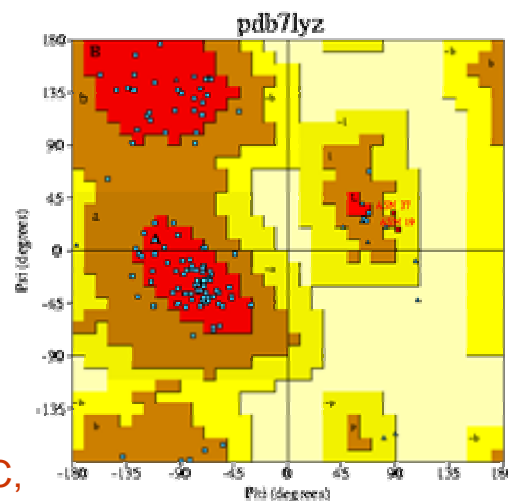

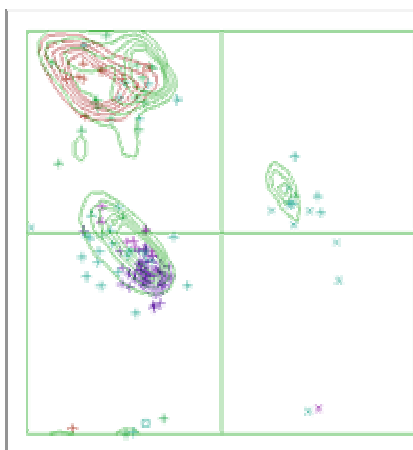

- Hydrophobic residues exposed
- Buried polar or ionic residues without the charges satisfied (H-bonds, salt-bridge etc)
- Clashes
- Unusual bond-lengths, bond-angles
- Sequence alignment is not-optimal
- Very large RMSD among the templates

Quality of Models

- Procheck: Stereo-chemical quality of the protein and residue by residue analysis in figures

<http://www.biochem.ucl.ac.uk/~roman/procheck/procheck.html>

- PDBREPORT: <http://www.cmbi.kun.nl/gv/pdbreport>

CASP: Test of the Models

- Critical Assessment of Techniques for Protein Structure

<http://predictioncenter.llnl.gov/>

- Showcase for the latest methods in the structure prediction area
- Once in two years
- Competition open in three areas
 - Homology Modeling, Threading and ab-initio
- CASP 1998, 2000 & 2002 showed the reliability of Homology Modeling when suitable templates are available (>30%, above Twilight Zone)

Database of Homology Models

- Project, 3D-Crunch (1984)
 - Project submitted all sequences of Swiss-Prot and trEMBL to SWISS MODEL server
- The resulting homology models (64,000) are stored and available to public from SWISS-MODEL Repository
 - Database contains: Final models, Entire modeling projects including aligned coordinates of templates

Database of Homology Models

- ModBase Sali and co-workers
 - Software used Modeller
 - Models were built based on spatial restraints
 - Restraints: distances between alpha carbons, distances within main-chain etc
 - E-minimization techniques are employed to obtain these restraints

Homology Modeling software in ABCC

Commercial Software:

- Tripos: Composer, Match-maker, GeneFold (not a HM software)
- Accelrys: Homology, Modeller
- GCG

Free Software:

- SWISS-MODEL, GeneMine
